# 1. The statement of the problem

NBA players are on average the highest-paid athletes in the world, according to Statista.com. The NBA players get paid an average salary of around 7.5 million. The median salary is about 3.8 million. The highest salary in the NBA for the 2016-2017 season is about 25 million, including superstar LeBron James from Cleveland Cavaliers.

Oftentimes sports players would seem to have major contracts with really high annual salaries (some people would even think they should not get paid so much).

Since of one our group members is a super fan of the NBA, he believes that those basketball players are paid by their season total performance. However, other members in our group think otherwise.

Through this project, we want to find out whether the NBA players and their season total performance have a strong positive correlation.

For this project, we would use the 2016-2017 season total performance and actual salaries to create a prediction model. Then, we fit the 2017-2018 season total performance to the prediction model, see the difference between the salaries we expected during 2017-2018 season and the actual salaries in 2017-2018.

#### Purpose:

- 1. Discover which predictors variables are critical to the salaries of the NBA players
- 2. Use a multiple regression model to predict NBA players' salaries
- 3. Examine the difference between the predicted salaries and actual salaries

## 2. Data Section

#### Data source

Our season total performance and salary data sets were collected from Basketball Reference (https://www.basketball-reference.com/)

#### Processing the data

1. Data set:

Combines NBA player performance and salary data by using player ID and team. During the regular season, some of the players will change their team, so they have two different performances and salaries.

2. Data cleaning:

We combined three datasets (NBA player salaries summary 1985-2018, season performance for both 2016-2017 and 2017-2018) from Basketball Reference. We joined the data sets based on the playerID and their team

names. Originally, the data set has a total of 34 variables, including 6 categorical variables, and 28 continuous variables.

In the first step of data cleaning, we removed 20 variables that seem to be either duplicated or are a combination of other variables. (i.e. trb = orb + drb). Later, we dropped the person who has the total performances as they transferred the teams during the season in order to focus on their performance.

# 3. Model Building Process

```
NBA <- read_csv("NBA.csv")</pre>
## Rows: 418 Columns: 35

## # ... with 3 more variables: tov <dbl>, pts <dbl>, `16_17_salary` <dbl>
```

#### Correlation Analysis

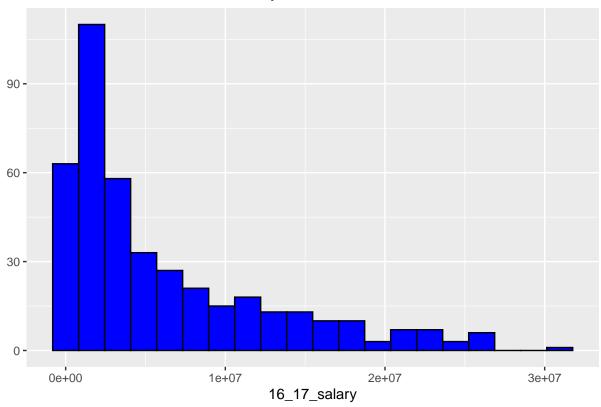

Based on the correlation plot, we can see the strongest linear relationship occurs between salary and points, although there could be a bit of a curvi-linear relationship. 3p, 2p, trb, ast, stl, tov have strong relationships as well.

#### Checking Y Predictable

# Distribution of 2016-2017 Salary

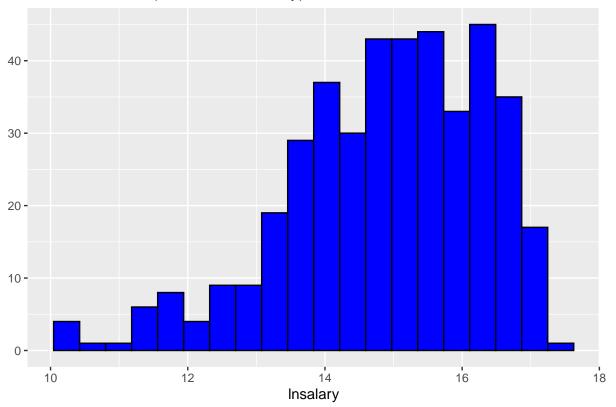

According to the histogram plot, we can see that the plot is right-skewed. To remedy the issue, we transformed the salary by taking logs.

#### Log Salary for Better Prediction

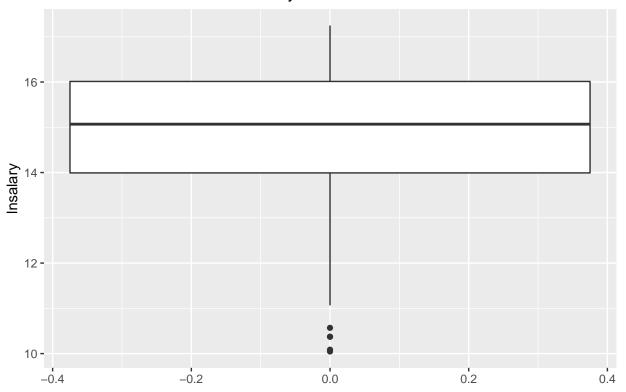

```
original_data %>%
  mutate(lnsalary = log(`16_17_salary`)) ->
  original_data

qplot(data = original_data, x = lnsalary, geom = "histogram",
    bins = 20, color = I("black"), fill = I("blue"),
    main = "Distribution of ln(2016-2017 Salary)")
```

# Distribution of In(2016–2017 Salary)

## Distribution of 2016–2017 Salary

Examining the histogram of log salary, we see possibly a very slight left skew, but it is closer to symmetric than without transform salary. According to the box plt, there are some of the outlines.

#### Original Model(only continuous variables)

```
original_data %>%
  select(-`16_17_salary`, -pos , -trans_team) ->
  new_og_data
og_model <- lm(lnsalary ~ ., data = new_og_data)</pre>
mult_og <- tidy(og_model)</pre>

According to the VIF, it shows our original model is good enough to be our final model, all of the variables

are less than 5.

#### Adding Dummy Variables - Insalary with 5 continuous predictors variables

We want to figure out will the position they play and transfer to different teams during the regular season influence their salaries?

Since some players had transferred teams during the season, we decided to create a dummy variable for transfer team or not (0=did not transfer, 1=transferred). We also created dummy variables for their positions to predict salary based on the position they played (c = center, pf = power forward, sf = small forward, pg = point guard, and sg = shooting guard; 0 = did not play in position, 1 = played in that position).

```
results <- dummy_cols(.data = reduce, select_columns = c("pos","trans_team"))
results %>%
  select(pos, pos_C, pos_PF, pos_PG, pos_SF, pos_SG, trans_team, trans_team_none,
         trans_team_trans) %>%
 head(6)
## # A tibble: 6 x 9

```

For the full model without dummy variables (12 variables)  $R_{adj}^2 = 0.4096448$  For the reduced model (5

## # ... with 3 more variables: deviance <dbl>, df.residual <int>, nobs <int>

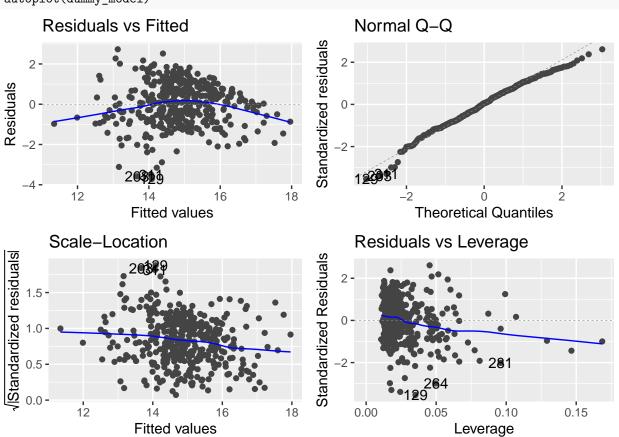

variables)  $R_{adj}^2 = 0.4095163$ 

For the reduce model including dummy variables (10 variables)  $R_{adj}^2 = 0.4455106$ 

In terms of  $R_{adj}^2$ , the reduce model including dummy variables does a better job fitting the data as it has the higher  $R_{adj}^2$ 

#### **Model Testing**

# # Assumtion autoplot(dummy\_model)

Based on the fitted residual plot, it seems some multi-linear regression assumptions are violated.

```
# Residual normality test
shapiro.test(dummy_model$residuals)
```

```
##
## Shapiro-Wilk normality test
##
## data: dummy_model$residuals
## W = 0.98822, p-value = 0.00187
```

According to the Shapiro-Wilk normality test with a test statistic of 0.99 and an associated p-value = 0.00187, since the p-value is below 0.05 which indicates the NBA Dummy data significantly deviate from a normal distribution.

```
# Residual independence test
durbinWatsonTest(dummy_model)
```

## lag Autocorrelation D-W Statistic p-value

```
##
             0.09443852
                              1.80766
                                        0.042
  Alternative hypothesis: rho != 0
```

- $H_0$  = residual from the regression are not auto-correlated (autocorrelation coefficient, p=0)
- $H_0$ : Alter = residuals from the regression are auto-correlated (AC, p > 0)

According to the Durbin-Watson test with a test statistic of 1.81 and an associated p-value = 0.024, since the

```
test statistic fell into the range of 0 to 2, which indicates that that there is a positive autocorrelation.
# Residual variance homogeneity test
ncvTest(dummy_model)
## Non-constant Variance Score Test
## Variance formula: ~ fitted.values
## Chisquare = 16.55129, Df = 1, p = 4.7352e-05
According to the non-constant variance score test with a chisquare 16.5513 and an associated p-value =
0.000047, which indicates that there has a heteroskedasticity issue.
# Testing for Non-Constant Variance Residual by using Breusch-Pagan
library(lmtest)
## Loading required package: zoo
##
## Attaching package: 'zoo'
##

bptest(dummy model)
##
##
    studentized Breusch-Pagan test
##
```

## data: dummy\_model ## BP = 28.039, df = 10, p-value = 0.001779 Test: \*  $H_0: \gamma_1 = 0 * H_1: \gamma_1 \neq 0$ 

According to the Breusch-Pagan Test with a test statistic = 28.039 and an associated p-value = 0.0018, under the assumption that  $H_0$  is true (variance of the disturbance terms is constant), it would be quite unlikely that we would observe a test statistic of our magnitude or larger.

Consequently, we can reject  $H_0$  and conclude there is a sufficient statistical evidence to indicate that the variance is changing relative to the magnitude of Insalary, which means we need to take further procedure to fix the issues.

As the results from several model testing, we can confirm there is some heteroskedascity issues with our residual and fitted value, as well as the residual normality.

#### Fixing Heteroskedasticity by Using WLS

Since the residual plot show that the error look like uneven distribution, it violates the assumption of homogeneity of variance. As the result, it has heterodasticity issue, so we solve this violation by using WLS.

```
refit <- lm(abs(residuals(dummy model)) ~ fitted(dummy model))</pre>
refit
```

```

• Reduce model:  $\widehat{ln(salary)} = 12.496 + 5.729 \cdot fg + 0.007 \cdot 3p + 0.002 \cdot 2p - 4.648 \cdot 2p + 0.001 \cdot trb + 0.198 \cdot posC + 0.412 \cdot posPF + 0.241 \cdot posPG + 0.424 \cdot posSF + 1.033 \cdot transteamnone$ 

NA

For the final model  $R_{adj}^2 = 0.436743$ .

Total 417 1131.9643 2.714543

Test Statistic: \*  $F = \frac{MSR}{MSE} = 33.334$  \* p-value < 0.00001

Conclusion. Given the test statistic F = 33.334 and its corresponding p-value < 0.00001. If none of the predictor variables were useful in explaining the variation we see in log salary, it would be almost impossible to observe a test statistic of our magnitude or greater.

Consequently, we will reject and conclude that there is overwhelming statistical evidence to indicate that at least one the predictor variables is useful in explaining the variation in log salary.

### # Assumtion autoplot(lm\_wls) Normal Q-Q Residuals vs Fitted Standardized residuals 2 -2 Residuals 0 -16 . 12 Fitted values **Theoretical Quantiles** Residuals vs Leverage Scale-Location /IStandardized residuals Standardized Residuals 1.5 -82 0.5 3133 0.0 12 0.10 16 0.00 0.05 Fitted values Leverage # Residual normality test shapiro.test(lm\_wls\$residuals) ## ## Shapiro-Wilk normality test ## data: lm\_wls\$residuals ## W = 0.98346, p-value = 0.0001044 # Residual independence test durbinWatsonTest(lm\_wls) ## lag Autocorrelation D-W Statistic p-value ## 0.09488015 1.80693 0.028 Alternative hypothesis: rho != 0 # Residual variance homogeneity test ncvTest(lm\_wls) ## Non-constant Variance Score Test ## Variance formula: ~ fitted.values ## Chisquare = 0.8191605, Df = 1, p = 0.36543

The model has followed all assumptions except residual normality test.

#### **Evaluate Forecast Model**

```
test <- read csv("player17 18.csv")
## Rows: 605 Columns: 31
## -- Column specification
## Delimiter: ","
## chr (5): Player, player_id, trans_team, Pos, Tm
## dbl (26): Age, G, GS, MP, FG, FGA, FG%, 3P, 3PA, 3P%, 2P, 2PA, 2P%, eFG%, FT...
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
names(test)[1:31] <- tolower(names(test)[1:31])</pre>
test_result <- dummy_cols(.data = test,</pre>
                           select_columns = c("pos", "trans_team"), remove_selected_columns = TRUE)
rename(.data = test_result, trans = trans_team_trans) -> test_dummy
# final reduce model
full_predict <- predict(lm_wls, newdata = test_dummy, interval = "confidence", level = 0.95)
## Warning in predict.lm(lm_wls, newdata = test_dummy, interval = "confidence", :
## prediction from a rank-deficient fit may be misleading
full_predict <- cbind(test_dummy, full_predict)</pre>
full predict1 <- full predict %>%
  left_join(NBA, by = c("player_id" = "player_id", "tm" = "tm")) %>%
  select(fit, `17_18salary`)
diff <- log(full predict1$`17 18salary`)-full predict1$fit</pre>
MAD <- mean(abs(diff), na.rm = TRUE)
MSE <- mean(diff^2,na.rm = TRUE)</pre>
```

We use a forecasting model to determine how well it does in producing accurate forecasts, not how well it fits the historical model. Measuring forecast accuracy, MAD=0.864, MSE=1.124.

From the result, both MAD and MSE are small and close to 0, actual values are very close to the predicted values. It means that the prediction model we done is working well.

#### 4. Inferences Based on the Model

After we build the multiple regression model, we can predict NBA players' salaries. The model has followed all assumptions except residual normality test.

Furthermore, the difference between predicted and actual salaries is small, which means that our model is great for applying.

#### 5. Further Directions

Since the data only offer the data that indicate players trans team during the regular season, isn't include off the season data that most of the palyers trans team time. For the further study, we recommend that add the resign the contrast or not, because the longer time interval model contrast effect maybe improve the results.
